Our approach works for arbitrary combinations of likelihood with prior.
No matrix inversion; no numerical derivatives.
Fully parallelizable block updates.
“But I can solve all of these with an $\ell^1$ constraint.”

True enough.

But consider an example: $p = 25; n = 500; 1000$ simulated data sets.

\[
y_i = 1_{z_i > 0} \quad \text{for } i = 1, \ldots, n
\]

\[
z \sim N(X\beta, I)
\]

\[
\beta = \begin{cases} 
\sqrt{5} & (5x) \\
0 & (20x)
\end{cases}
\]

A teaser example: logit with a bridge penalty

\[
\hat{\beta} = \arg \min_{\beta \in \mathbb{R}^p} \left\{ \sum_{i=1}^{n} \log(1 + \exp\{-y_i x_i^T \beta\}) + \sum_{j=1}^{p} |\beta_j / \tau s_j|^\alpha \right\}
\]
A teaser example: logit with a bridge penalty

\[ \hat{\beta} = \arg \min_{\beta \in \mathbb{R}^p} \left\{ \sum_{i=1}^{n} \log(1 + \exp\{-y_i x_i^T \beta\}) + \sum_{j=1}^{p} |\beta_j / \tau s_j|^{\alpha} \right\} \]
To find the MAP, just iterate three steps

\[
\beta^{(g+1)} = \left( \tau^{-2} S^{-1} \hat{\Lambda}^{-1(g)} + X_*^T \hat{\Omega}^{-1(g)} X_* \right)^{-1} \left( \frac{1}{2} X_*^T 1 \right)
\]

\[
\hat{\omega}^{-1(g+1)}_i = \frac{1}{z_i^{(g)}} \left\{ \frac{e^{z_i^{(g)}}}{1 + e^{z_i^{(g)}}} - \frac{1}{2} \right\}
\]

\[
\hat{\lambda}^{-1(g+1)}_j = \alpha (\tau s_j)^{2-\alpha} |\beta_j^{(g)}|^{\alpha-2}
\]
To find the MAP, just iterate three steps

Don’t actually do this.

\[
\beta^{(g+1)} = \left( \tau^{-2} S^{-1} \hat{\Lambda}^{-1(g)} + X^T_* \hat{\Omega}^{-1(g)} X_* \right)^{-1} \left( \frac{1}{2} X^T_* 1 \right)
\]

\[
\hat{\omega}_{-1(g+1)} = \frac{1}{z_i^{(g)}} \left\{ \frac{e^{z_i^{(g)}}}{1 + e^{z_i^{(g)}}} - \frac{1}{2} \right\}
\]

\[
\hat{\lambda}_{-1(g+1)} = \alpha (\tau s_j)^{2-\alpha} |\beta_j^{(g)}|^{-\alpha-2}
\]
Example: covariate-dependent disease networks

~112m patient records comprising ICD-9 codes + prescriptions + covariates

ISCHEMIC HEART DISEASE (410-414)
410 Acute myocardial infarction
410.0 Of anterolateral wall
410.1 Of other anterior wall
410.2 Of inferolateral wall
410.3 Of inferoposterior wall
410.4 Of other inferior wall
410.5 Of other lateral wall
410.6 True posterior wall infarction
410.7 Subendocardial infarction
410.8 Of other specified sites
410.9 Unspecified site

Our approach: a tree of graphs

Tree splits on covariates, mainly demographics and geography.

Each terminal node is a disease network for a subgroup of the population.

Goh et. al., PNAS (2007)
The big picture

We use normal variance–mean mixtures to represent a wide class of objective functions commonly encountered in high-dimensional problems.

By modern Bayesian standards, these are pretty simple.

But they are ubiquitous, useful, and often the only tractable approach in their respective domains for data sets beyond a certain size.
This class is surprisingly broad. For example:

\[ p(\alpha_{1:K}, \beta_{1:N_d} \mid W, \mu, \Sigma) \propto \prod_{d=1}^{D} \left\{ p(\beta_d \mid \mu, \Sigma) \cdot \prod_{n=1}^{N_d} \left[ \sum_{k=1}^{K} \left( \frac{e^{\beta_{dk}}}{\sum_{l=1}^{K} e^{\beta_{dl}}} \right) \alpha_{k,n} \right] \right\} \cdot p(\alpha_{1:K}) \]

We get an exact MAP estimate.
No variational approximation.
This class is surprisingly broad. For example:

\[ p(\alpha_{1:K}, \beta_{1:Nd} \mid W, \mu, \Sigma) \propto \prod_{d=1}^{D} p(\beta_d \mid \mu, \Sigma) \cdot \prod_{n=1}^{Nd} \left\{ \sum_{k=1}^{K} \left( \frac{e^{\beta_{dk}}}{\sum_{l=1}^{K} e^{\beta_{dl}}} \right) \alpha_{k,w_n} \right\} \cdot p(\alpha_{1:K}) \]

(e.g. Blei and Lafferty, 2009)

We get an exact MAP estimate.
No variational approximation.
Connection with previous work

Penalties/priors corresponding to scale mixtures:
- lasso (Tibshirani, 1996; Park and Casella, 2008; Hans, 2009)

- Penalties, priors, and Lévy processes (Polson and Scott, 2011)
The standard scale-mixture trick

\[ p(z) = \int_{0}^{\infty} \phi(z \mid v) p(v) \, dv \]
\begin{align*}
\hat{\beta} &= \text{arg min} \left\{ \| y - X \beta \|^2 + \nu \sum_{j=1}^{p} g(\beta_j) \right\} \\
&\uparrow \\
(y | \beta) &\sim \mathcal{N}(X \beta, \sigma^2 \beta) \\
(\beta_i | \tau^2, \lambda_i^2) &\sim \mathcal{N}(0, \tau^2 \lambda_i^2) \\
\lambda_i^2 &\sim \pi(\lambda_i^2) \\
(\tau^2, \sigma^2) &\sim \pi(\tau^2, \sigma^2) \\
(\beta | y, \tau^2, \Lambda, \sigma^2) &\sim \mathcal{N}(\hat{\beta}, \hat{\Sigma}_\beta) \\
\hat{\beta} &= (\tau^{-2} \Lambda^{-1} + X^TX)^{-1} X^T y
\end{align*}
\[
\hat{\beta} = \arg\min \left\{ ||y - X\beta||^2 + \nu \sum_{j=1}^{p} g(\beta_j) \right\}
\]

\[
(y | \beta) \sim N(X\beta, \sigma^2 \beta)
\]

\[
(\beta_i | \tau^2, \lambda^2_i) \sim N(0, \tau^2 \lambda^2_i)
\]

\[
\lambda^2_i \sim \pi(\lambda^2_i)
\]

\[
(\tau^2, \sigma^2) \sim \pi(\tau^2, \sigma^2)
\]

Exponential $\rightarrow$ Lasso
Inverted-beta $\rightarrow$ Horseshoe
Gamma $\rightarrow$ Normal/gamma
(Andrews and Mallows; West)

\[
(\beta | y, \tau^2, \Lambda, \sigma^2) \sim N(\hat{\beta}, \hat{\Sigma}_\beta)
\]

\[
\hat{\beta} = (\tau^{-2} \Lambda^{-1} + X^T X)^{-1} X^T y
\]
The standard scale-mixture trick

\[ p(z) = \int_0^\infty \phi(z | v) p(v) \, dv \]
The standard scale-mixture trick

\[ p(z) = \int_{0}^{\infty} \phi(z \mid \nu) p(\nu) \, d\nu \]

Two ways of generalizing this:

- the Lévy representation
- variance-mean mixtures
1) The Lévy representation

Let \( \psi(t), t > 0, \) be a nonnegative-real-valued, totally monotone function such that \( \lim_{t \to 0} \psi(t) = 0. \)

**Part A:** Suppose that these conditions are met for \( t \equiv f(\beta_j). \) Then the prior distribution \( p(\beta_j | s) \propto \exp\{-s \psi[f(\beta_j)]\} \), where \( s > 0, \) is the moment-generating function of a subordinator \( T(s), \) evaluated at \( f(\beta_j), \) whose Lévy measure satisfies

\[
\psi(t) = \int_0^\infty \{1 - \exp(-tx) \} \mu(dx). \tag{1}
\]

**Part B:** Suppose that these conditions are met for \( t \equiv \beta_j^2/2. \) Then \( p(\beta_j | s) \propto \exp\{-s \psi(\beta_j^2/2)\}, \) where \( s > 0, \) is a mixture of normals given by

\[
p(\beta_j | s) \propto \int_0^\infty N(\beta_j | 0, T^{-1}) T^{-1/2} p(T) \, dT,
\]

where \( p(T) \) is the density of the subordinator \( T, \) observed at time \( s, \) whose Lévy measure \( \mu(dx) \) satisfies (1).
I) The Lévy representation

Let $\psi(t), \ t > 0$, be a nonnegative-real-valued, totally monotone function such that $\lim_{t \to 0} \psi(t) = 0$.

Part A: Suppose that these conditions are met for $t \equiv f(\beta_j)$. Then the prior distribution $p(\beta_j \mid s) \propto \exp\{ -s \psi[f(\beta_j)] \}$, where $s > 0$, is the moment-generating function of a subordinator $T(s)$, evaluated at $f(\beta_j)$, whose Lévy measure satisfies

$$\psi(t) = \int_{0}^{\infty} \{1 - \exp(-tx)\} \mu(dx). \quad (1)$$

Part B: Suppose that these conditions are met for $t \equiv \beta_j^2/2$. Then $p(\beta_j \mid s) \propto \exp\{ -s \psi(\beta_j^2/2) \}$, where $s > 0$, is a mixture of normals given by

$$p(\beta_j \mid s) \propto \int_{0}^{\infty} N(\beta_j \mid 0, T^{-1}) \ T^{-1/2} \ p(T) \ dT,$$

where $p(T)$ is the density of the subordinator $T$, observed at time $s$, whose Lévy measure $\mu(dx)$ satisfies (1).

(super useful for block-wise penalties, e.g. the group lasso)
2) Mean-variance mixtures

\[ p(z) = \int_0^{\infty} \phi(z | v) p(v) \, dv \]

\[ p(z) = \int_0^{\infty} \phi(z | \mu + kv, v) p(v) \, dv \]

(like Brownian motion with a drift; useful for non-Gaussian likelihoods)
The generic regularization problem

\[ Q(\beta) = \sum_{i=1}^{n} f(y_i, x_i^T \beta) + \sum_{j=1}^{p} g \left( \frac{\beta_j}{\tau s_j} \right) \]

We consider properties of the posterior distribution

\[ e^{-Q(\beta)} \propto p(\beta | \tau, y) \propto \exp \left\{ -\sum_{i=1}^{n} f(y_i, x_i^T \beta) - \sum_{j=1}^{p} g(\beta_j / \tau s_j) \right\} \]

\[ \propto \left\{ \prod_{i=1}^{n} p(z_i | x_i^T \beta) \right\} \left\{ \prod_{j=1}^{k} p(\beta_j | \tau) \right\} \]

\[ = p(z | \beta) \cdot p(\beta | \tau), \]

where \( z_i = y_i - x_i^T \beta \) for regression, or \( z_i = y_i x_i^T \beta \) for classification.
The generic regularization problem

Suppose that both the likelihood and prior/penalty can be represented as normal variance-mean mixtures.

\[
p(z_i \mid \beta) = \int_0^\infty \phi(z_i \mid \mu_z + x_z \omega_i, \sigma^2 \omega_i) \, dP(\omega_i)
\]

\[
p(\beta_j \mid \tau) = \int_0^\infty \phi(\beta_j \mid \mu_\beta + x_\beta \lambda_j, \tau^2 s_i^2 \lambda_j) \, dP(\lambda_j).
\]
Then we have an easy EM:

**E Step**

Compute the expected value of the log posterior, given the current parameter estimate:

$$Q(\beta | \beta^{(g)}) = \int \log p(\beta | \omega, \lambda, \tau, y) p(\omega, \lambda | \beta^{(g)}, \tau, y) \, d\omega \, d\lambda.$$

**M Step**

Maximize the complete-data posterior to update the parameter estimate:

$$\beta^{(g+1)} = \arg \max_\beta Q(\beta | \beta^{(g)}).$$
The E Step

The observed-data log posterior is

\[ p(\beta | \tau, y) = \int \pi(\beta | \omega, \lambda, y) \, p(\omega, \lambda | y, \tau) \, d\omega \, d\lambda. \]

Exploiting the mean–variance mixture representation, the complete-data log posterior is

\[ \log p(\beta | \omega, \lambda, \tau, y) = c_0(\omega, \lambda, y, \tau) - \frac{1}{2} \sum_{i=1}^{n} \omega_i^{-1} (z_i - \mu_z - \chi_y \omega_i)^2 \]

\[ - \frac{1}{2s^2 \tau^2} \sum_{j=1}^{p} \lambda_j^{-1} (\beta_j - \mu_\beta - \chi_\beta \lambda_j)^2 \]

This can be shown to depend linearly upon the conditional moments \( \{\hat{\omega}_i^{-1}\} \) and \( \{\hat{\lambda}_j^{-1}\} \). Therefore the E-step is to simply plug these conditional expected values into the complete-data log posterior.
The E Step

Theorem: these conditional moments are:

$$(\beta_j - \mu_\beta) \hat{\lambda}_j^{-1(g)} = x_\beta + \tau^2 s_j^2 \ g'(\beta_j \mid \tau) ,$$

$$(z_i - \mu_z) \hat{\omega}_i^{-1(g)} = x_z + \sigma^2 \ f'(z_i \mid \beta) ,$$

Key fact: we don’t need the conditional posterior for the latent variances.

Only need the functional form of the likelihood (f) and prior (g).

These are pre-specified.
Tilted, iteratively re-weighted least squares

E step

Given a current estimate \( \beta = \beta^{(g)} \), compute the conditional moments of the latent variances as

\[
(\beta_j^{(g)} - \mu_\beta) \hat{\lambda}_j^{-1} = \chi_\beta + \tau^2 s_j^2 g'(\beta_j^{(g)} | \tau),
\]

\[
(z_i^{(g)} - \mu_z) \hat{\omega}_i^{-1} = \chi_z + \sigma^2 f'(z_i^{(g)} | \beta).
\]

M Step

For regression, compute \( \beta^{(g+1)} \) as

\[
\beta^{(g+1)} = \left( \tau^{-2} S^{-1} \hat{\Lambda}^{-1} + X^T \hat{\Omega}^{-1} X \right)^{-1} X^T \left( \hat{\Omega}^{-1} y - \mu_z \omega^{-1} - \chi_z 1 \right).
\]

For classification, compute \( \beta^{(g+1)} \) as

\[
\beta^{(g+1)} = \left( \tau^{-2} S^{-1} \hat{\Lambda}^{-1} + X_*^T \hat{\Omega}^{-1} X_* \right)^{-1} X_*^T \hat{\Omega}^{-1} \left( \mu_z 1 + \chi_z \hat{\omega}^{(g)} \right).
\]
This works for a broad class of models.

+ multinomial logit, autologistic, topic models, RBMs, extreme-value . . . .
Two key identities:

\[
\frac{\alpha^2 - \chi^2}{2\alpha} e^{-\alpha|\theta-\mu|+\chi(\theta-\mu)} = \int_0^\infty \phi(\theta \mid \mu + \chi v, v)) \ p_{gig}(v \mid 1, 0, \sqrt{\alpha^2 - \chi^2}) \ dv
\]

\[
\frac{1}{B(\alpha, \chi)} \frac{e^{\alpha(\theta-\mu)}}{(1 + e^{\theta-\mu})^{2(\alpha-\chi)}} = \int_0^\infty \phi(\theta \mid \mu + \chi v, v) \ p_{pol}(v \mid \alpha, \alpha - 2\chi) \ dv.
\]

Improper versions (treat purely as an integral identity)

\[
a^{-1} \exp \left\{ -2c^{-1} \max(au, 0) \right\} = \int_0^\infty \phi(u \mid -av, cv) \ dv
\]

\[
c^{-1} \exp \left\{ -2c^{-1} \rho_q(u) \right\} = \int_0^\infty \phi(u \mid -(2\tau - 1)v, cv) e^{-2\tau(1-\tau)v} \ dv
\]

\[
(1 + \exp\{u - \mu\})^{-1} = \int_0^\infty \phi(u \mid \mu - (1/2)v, v) \ p_{pol}(v \mid 0, 1) \ dv
\]

where \( \rho_q(u) = \frac{1}{2}|u| + \left(q - \frac{1}{2}\right) u \) is the check-loss function.
Back to the teaser example: logit models

A Polya mixing distribution . . .

\[ p_{pol}(\nu \mid \alpha, \alpha - 2k) = \sum_{k=0}^{\infty} w_k e^{-a_k \nu} \]

The terms in this sum are

\[ a_k = \frac{(\alpha + k)(k + k)}{2} \]

\[ w_k = a_k \prod_{j \neq k} \left( \frac{a_k}{a_j - a_k} \right) = \binom{-2\delta}{k} \frac{(\delta + k)}{B(\delta + b, \delta - b)}, \]

where \( b = \frac{1}{2}(\alpha - k), \delta = \frac{1}{2}(\alpha + k), \) and \( \binom{-2\delta}{k} = \frac{(-1)^k(2\delta)\ldots(2\delta+k-1)}{k!}. \)
A Polya mixing distribution leads to a $Z$ distribution marginal.

$$p_Z(\theta \mid \mu, \alpha, k) = \frac{1}{B(\alpha, k)} \frac{(e^{\theta - \mu})^\alpha}{(1 + e^{\theta - \mu})^{2(\alpha-k)}}$$

This family includes the logistic regression model as a limiting, improper case: $(a, k, \mu) = (1, 1/2, 0)$.

Our representation theorem gives the relevant conditional moment as

$$\hat{\omega}_i^{-1} = \frac{1}{z_i} \left\{ \frac{e^{z_i}}{1 + e^{z_i}} - \frac{1}{2} \right\}, \quad z_i = y_i x_i^T \beta$$
Multinomial logit

The probability that observation $i$ falls into class $k$ is

$$
\theta_{ki} = P(y_i = k) = \frac{\exp(x_i^T \beta_k)}{\sum_{l=1}^{K} \exp(x_i^T \beta_l)}
$$

To represent the multinomial logit model in our framework, let

$$
\eta_{ki} = \exp \left( x_i^T \beta_k - c_{ki} \right) / \left\{ 1 + \exp \left( x_i^T \beta_k - c_{ki} \right) \right\}
$$

$$
c_{ki}(\beta_{(-k)}) = \log \sum_{l \neq k} \exp \{ x_i^T \beta_l \}
$$

(Holmes and Held, 2006)
Multinomial logit

Write the conditional likelihood for category k as

\[
L(\beta_k \mid \beta_{(-k)}, y) \propto \prod_{i=1}^{n} \prod_{l=1}^{K} \theta_{yl}^{\tilde{y}_{li}}
\]

\[
\propto \prod_{i=1}^{n} \eta_{ki}^{\tilde{y}_{ki}} \{w_i(1 - \eta_{ki})\}^{1-\tilde{y}_{ki}}
\]

\[
\propto \prod_{i=1}^{n} \eta_{ki}^{\tilde{y}_{ki}} \{(1 - \eta_{ki})\}^{1-\tilde{y}_{ki}}
\]

\[
\propto \prod_{i=1}^{n} \left\{ \frac{\exp(\gamma_{ki} x_i^T \beta_k - \gamma_{ki} c_{ki})}{1 + \exp(\gamma_{ki} x_i^T \beta_k - \gamma_{ki} c_{ki})} \right\}
\]

\[
= \prod_{i=1}^{n} \int_{0}^{\infty} \phi(z_{ki} \mid \mu_{ki} + x \xi_{ki}, \xi_{ki}) \ p_{PY}(\xi_{ki} \mid 1, 0) \ d\xi_{ki}
\]

where \( x = 1/2, z_{ki} = \gamma_{ki} x_i^T \beta_k, \mu_{ki} = \gamma_{ki} c_{ki}, \) and \( p_{PY}(\xi_{ki} \mid 1, 0) \) is a function of \( \xi_{ki} \) that is the limit of a Polya density as \( b \to 0 \).
An exact ECM

For iteration $t = 1, 2, \ldots$

For $k = 2, \ldots, K$, cycle through the following steps:

Update $\Omega_k$:

$z_{ki}^{(t)} := \gamma_{ki} x_i^T \beta_k^{(t)}$

$\mu_{ki}^{(t)} := \gamma_{ki} \log \sum_{l \neq k} \exp(x_i^T \beta_l^{(t)})$

$\omega_{ki}^{(t)} := \left( \frac{1}{z_{ki}^{(t)} - \mu_{ki}^{(t)}} \right) \left( \frac{\exp \left\{ z_{ki}^{(t)} - \mu_{ki}^{(t)} \right\}}{1 + \exp \left\{ z_{ki}^{(t)} - \mu_{ki}^{(t)} \right\}} - \frac{1}{2} \right)$

$\Omega_k^{(t)} := \text{diag}(\omega_{k1}^{(t)}, \ldots, \omega_{kn}^{(t)})$,

where $\beta_k^{(t)}$ is the current estimate for the $k$th block of coefficients, and where $\gamma_{ki} = \pm 1$ is an indicator of whether $y_i = k$. 
An exact ECM

For iteration $t = 1, 2, \ldots$

For $k = 2, \ldots, K$, cycle through the following steps:

**Update $\Lambda_k$:**

\[
\lambda_{kj} := \frac{\tau^2 \psi'(\beta_{kj}^{(t)}/\tau)}{\beta_{kj}^{(t)}}
\]

\[
\Lambda_k^{(t)} := \text{diag}(\lambda_{k1}^{(t)}, \ldots, \lambda_{kp}^{(t)})
\]

where $\psi'$ is the derivative of the penalty function $\psi(\beta_{kj})$. 
An exact ECM

For iteration $t = 1, 2, \ldots$

For $k = 2, \ldots, K$, cycle through the following steps:

**Update $\beta_k$:** Solve the linear system $A_k^{(t)} \beta_k^{(t+1)} = b_k^{(t)}$ for $\beta_k^{(t+1)}$, with

$$A_k^{(t)} := \tau^{-2} \Lambda_k^{(t)} + \tilde{X}_k^T \Omega_k^{(t)} \tilde{X}_k$$

$$b_k^{(t)} := \tilde{X}_k^T \left( \Omega_k^{(t)} \mu_k^{(t)} + \frac{1}{2} 1 \right),$$

where $\tilde{X}_k$ is the $n \times p$ matrix having rows $\tilde{x}_i = \gamma_{ki} x_i$, $1$ is a column vector of ones, and $\mu_k^{(t)} = (\mu_k^{(t)}_{k1}, \ldots, \mu_k^{(t)}_{kn})^T$. 

An exact ECM

For iteration $t = 1, 2, \ldots$

For $k = 2, \ldots, K$, cycle through the following steps:

**Update $\beta_k$:** Solve the linear system $A_k^{(t)} \beta_k^{(t+1)} = b_k^{(t)}$ for $\beta_k^{(t+1)}$, with

$$
A_k^{(t)} := \tau^{-2} \Lambda_k^{(t)} + \tilde{X}_k^T \Omega_k^{(t)} \tilde{X}_k
$$
$$
b_k^{(t)} := \tilde{X}_k^T \left( \Omega_k^{(t)} \mu_k^{(t)} + \frac{1}{2}1 \right),
$$

where $\tilde{X}_k$ is the $n \times p$ matrix having rows $\tilde{x}_i = \gamma_{ki} x_i$, $1$ is a column vector of ones, and $\mu_k^{(t)} = (\mu_{k1}^{(t)}, \ldots, \mu_{kn}^{(t)})^T$.

Don’t solve this exactly.
Tilted, iteratively re-weighted conjugate gradient

In the update step for $\beta$, don’t solve the system exactly. Instead:

While $|\Delta_{(t,l)}| > \delta_{\text{min}}$, increment $l$ and set

$$
\beta^{(c,l)} := \beta^{(c,l-1)} + \Delta_{(t,l-1)} \\
r_{(t,l)} := r_{(t,l-1)} - \alpha_{(t,l-1)} c_{(t,l-1)} \\
\gamma_{(t,l)} := \frac{r^T_{(t,l)} r_{(t,l)}}{r^T_{(t,l-1)} r_{(t,l-1)}} \\
d_{(t,l)} := r_{(t,l)} + \gamma_{(t,l)} d_{(t,l-1)} \\
c_{(t,l)} := A_k^{(t)} d_{(t,l)} \\
\alpha_{(t,l)} := \frac{r^T_{(t,0)} r_{(t,l)}}{d^T_{(t,l)} c_{(t,l)}} \\
\Delta_{(t,l)} := \alpha_{(t,l)} d_{(t,l)} .
$$
Tilted, iteratively re-weighted conjugate gradient

In the update step for $\beta$, don’t solve the system exactly. Instead:

While $|\Delta_{(t,l)}| > \delta_{\min}$, increment $l$ and set

$$
\begin{align*}
\beta^{(c,l)} & := \beta^{(c,l-1)} + \Delta_{(t,l-1)} \\
\gamma_{(t,l)} & := \begin{pmatrix} \gamma_{(t,l)} \end{pmatrix} \\
\gamma_{(t,l)} & := \begin{pmatrix} \gamma_{(t,l)} \end{pmatrix} \\
\lambda_{(t,l)} & := \begin{pmatrix} \lambda_{(t,l)} \end{pmatrix} \\
\Delta_{(t,l)} & := \begin{pmatrix} \Delta_{(t,l)} \end{pmatrix} \\
\end{align*}
$$

Parallelize this. $c_{(t,l)} := A^{(t)}_{k} d_{(t,l)}$

$$
\begin{align*}
\beta^{(c,l)} & := \beta^{(c,l-1)} + \Delta_{(t,l-1)} \\
\gamma_{(t,l)} & := \begin{pmatrix} \gamma_{(t,l)} \end{pmatrix} \\
\gamma_{(t,l)} & := \begin{pmatrix} \gamma_{(t,l)} \end{pmatrix} \\
\lambda_{(t,l)} & := \begin{pmatrix} \lambda_{(t,l)} \end{pmatrix} \\
\Delta_{(t,l)} & := \begin{pmatrix} \Delta_{(t,l)} \end{pmatrix} \\
\end{align*}
$$

While $|\Delta_{(t,l)}| > \delta_{\min}$, increment $l$ and set

$$
\begin{align*}
\beta^{(c,l)} & := \beta^{(c,l-1)} + \Delta_{(t,l-1)} \\
\gamma_{(t,l)} & := \begin{pmatrix} \gamma_{(t,l)} \end{pmatrix} \\
\gamma_{(t,l)} & := \begin{pmatrix} \gamma_{(t,l)} \end{pmatrix} \\
\lambda_{(t,l)} & := \begin{pmatrix} \lambda_{(t,l)} \end{pmatrix} \\
\Delta_{(t,l)} & := \begin{pmatrix} \Delta_{(t,l)} \end{pmatrix} \\
\end{align*}
$$

Parallelize this. $c_{(t,l)} := A^{(t)}_{k} d_{(t,l)}$

$$
\begin{align*}
\beta^{(c,l)} & := \beta^{(c,l-1)} + \Delta_{(t,l-1)} \\
\gamma_{(t,l)} & := \begin{pmatrix} \gamma_{(t,l)} \end{pmatrix} \\
\gamma_{(t,l)} & := \begin{pmatrix} \gamma_{(t,l)} \end{pmatrix} \\
\lambda_{(t,l)} & := \begin{pmatrix} \lambda_{(t,l)} \end{pmatrix} \\
\Delta_{(t,l)} & := \begin{pmatrix} \Delta_{(t,l)} \end{pmatrix} \\
\end{align*}
$$

Parallelize this. $c_{(t,l)} := A^{(t)}_{k} d_{(t,l)}$

$$
\begin{align*}
\beta^{(c,l)} & := \beta^{(c,l-1)} + \Delta_{(t,l-1)} \\
\gamma_{(t,l)} & := \begin{pmatrix} \gamma_{(t,l)} \end{pmatrix} \\
\gamma_{(t,l)} & := \begin{pmatrix} \gamma_{(t,l)} \end{pmatrix} \\
\lambda_{(t,l)} & := \begin{pmatrix} \lambda_{(t,l)} \end{pmatrix} \\
\Delta_{(t,l)} & := \begin{pmatrix} \Delta_{(t,l)} \end{pmatrix} \\
\end{align*}
$$

Parallelize this. $c_{(t,l)} := A^{(t)}_{k} d_{(t,l)}$.
Other methods

You can solve many of these problems using tailored methods—but not all of them, and rarely this simply or efficiently.

**LARS**: efficient only in Gaussian models

**Coordinate descent**: can get stuck; may require numerical derivatives; irredeemably serial

**LLA/LQA**: exact only in Gaussian models (where it’s a special case of our method)

**Variational methods**: never exact; sometimes inconsistent; poor in cases of interesting a posteriori dependence
How would you do MCMC in this class?

Some people have worked out special cases.

Here’s an interesting fact:

\[
\begin{align*}
p_{\text{pol}}\left(\frac{1}{2}, \frac{1}{2}\right)(\lambda) & = \sum_{n=0}^{\infty} (-1)^n \left(n + \frac{1}{2}\right) e^{-\frac{1}{2} \left(n + \frac{1}{2}\right)^2 \lambda} \\
C & \stackrel{D}{=} \frac{1}{4\pi^2} \lambda
\end{align*}
\]

\[
\begin{align*}
p(C) & = 4\pi^2 \sum_{n=0}^{\infty} (-1)^n \left(n + \frac{1}{2}\right) e^{-2 \left(n + \frac{1}{2}\right)^2 \pi^2 C} \\
C & \stackrel{D}{=} \frac{1}{2\pi^2} \sum_{n=1}^{\infty} \frac{\mathcal{E}(1)}{(n - \frac{1}{2})^2}
\end{align*}
\]
How would you do MCMC in this class?

There is a duality between the scale-mixture and MGF representations for C:

\[
\mathbb{E}\left(e^{-\frac{x^2}{2}C}\right) = \mathbb{E}\left((2\pi C)^{-\frac{1}{2}} e^{-\frac{x^2}{8\pi^2 C}}\right) = \frac{1}{\cosh\left(\frac{x}{2}\right)}
\]

A logit-type likelihood would thus look like

\[
\frac{2^{a+b} e^{ax}}{(1 + e^x)^{a+b}} = e^{\frac{1}{2}(a-b)x} \cdot \left(\frac{1}{\cosh\left(\frac{x}{2}\right)}\right)^{a+b}
\]

\[
= e^{\frac{1}{2}(a-b)x} \cdot \mathbb{E}\left(e^{-\frac{x^2}{2}C}\right)
\]
How would you do MCMC in this class?

Therefore we can simulate from $C$ using Polya-Gamma distributions:

\[
(C \mid x) \overset{D}{=} 2 \sum_{n=1}^{\infty} \frac{\mathcal{G}(a + b, 1)}{a_n} \\
\]

\[
a_n = \frac{1 + \frac{x^2}{4(n - \frac{1}{2})^2 \pi^2}}{4 \left( n - \frac{1}{2} \right)^2 \pi^2}
\]
The theory of variance-mean mixtures allows MAP estimation for arbitrary combinations of model (left) with prior or penalty (right).

With the conjugate-gradient version, there are no matrix inverses and no numerical derivatives.
